MELBOURNE AND METROPOLITAN TRAMWAYS BOARD

ENGINEERING DEPARTMENT

PLANNING BRANCH

When a distinction should be made between what may be taken as a desirable length and what is generally accepted as minimum.

DESIGN OF TRACKS

When a distinction should be made between what may be taken as a desirable length and what is generally accepted as minimum.

DESIGN LENGTH

- (a) Cross gradient should not be greater than 1/100 (British Railway Practice).
- (b) Rate of gain (or loss) of earth should not be greater than 2 1/2 inches per cent (British Railway Practice).

HORIZONTAL CURVES

GENERAL ARRANGEMENT AND SELECTION

The corresponding minimum lengths of transitions from straight to circular curves with 4 ft wide gauge are given in a column of 0.1g rise values are as follows:

	100	200	300	400	500	600
Length	40	30	20	15	12	10
Rate of gain	1.0	0.5	0.3	0.2	0.15	0.12
Rate of loss	1.0	0.5	0.3	0.2	0.15	0.12
Rate of gain of 1 in 100	1.0	0.5	0.3	0.2	0.15	0.12
Rate of loss of 1 in 100	1.0	0.5	0.3	0.2	0.15	0.12
Rate of gain of 1 in 200	1.0	0.5	0.3	0.2	0.15	0.12
Rate of loss of 1 in 200	1.0	0.5	0.3	0.2	0.15	0.12

DESIGN LENGTH

- (a) Cross gradient should not be less than 1/100 (British Railway Practice).
- (b) Rate of gain (or loss) of earth should not be greater than 2 1/2 inches per cent (British Railway Practice).
- (c) The bulk of the earth should not be greater than 2 1/2 inches per cent (British Railway Practice).

This is of course an empirical formula based on a cross of 1.75 feet per cent and a limit of 2 1/2 inches per cent is raised. It is likely that the British Railway authorities are not as a matter properly considered.

MAY 1966.

HORIZONTAL CURVES - GENERAL ARRANGEMENT & SELECTION.

Where changes in track direction occur it is necessary to design the curved track to permit the maximum operating speeds. This requires the optimum arrangement of circular curvature and transition to and from the straight or tangent track.

1. Length of Transition.

Here a distinction should be made between what may be regarded as a desirable length and what is generally accepted as a minimum.

1.1 Minimum Length.

- (a) Cant gradient should not be greater than $1/300$ (British Railway Practice).
- (b) Rate of gain (or loss) of cant should not be greater than $2\frac{1}{4}''$ inches per second. (British Railway Practice).
- (c) The build up of the centrifugal force term v^2/R should not be greater than 2 ft. per second³. (Reference Plane & Geodetic Surveying Part 1 - Clark).

The corresponding minimum lengths of transitions from straight track to circular curves with 6 inches cant and speeds to give a maximum of 0.1g side thrust are as follows:-

Radius ft.	150	200	300	400	500	600
Max. Speed m.p.h.	22 <i>19½</i>	25 <i>22½</i>	30 <i>27</i>	35 <i>31½</i>	39 <i>35½</i>	42 <i>39</i>
Lth. to give cant gradient = $1/300$	100	100	100	100	100	100
Lth. to give rate of gain of cant of $2\frac{1}{4}''$ per sec.	-	-	-	-	152	168
Lth. to give a gain of v^2/R of 2 ft. per sec ³ .	-	-	<i>102</i>	120	140	155

*figures for 4"
cant in tunnel*

17.8

1.2 Desirable length.

- (a) Cant gradient should not be less than $1/450$ (British Railway Practice).
- (b) Rate of gain (or loss) of cant should not be greater than $1\frac{1}{2}''$ per second (British Railway Practice).
- (c) The build up of the centrifugal force term v^2/R should not be greater than "a" ft. per sec³ where "a" = $1.75 - 0.0075 V$ and V is the maximum speed in miles per hour. (Reference Plane and Geodetic Surveying Part 1 - Clark).

This is of course an empirical formula based on a maximum of 1.75 feet per sec³ and a linear reduction as the maximum speed is raised. It is little more than a compromise whereas British Railway recommendations are based on a number of properly conducted trials.

The corresponding desirable lengths of transitions from straight track to circular curves with 6 inches cant and speeds to give a maximum of 0.1g side thrust are as follows:-

Radius ft.	150	200	300	400	500	600
Max. Speed m.p.h.	19 ^{1/2} 22	22 ^{1/2} 25	27 30	31 ^{1/2} 35	35 ^{1/2} 39	39 42
Lth. to give cant gradient = 1/450	150 225	150 225	150 225	150 225	150 225	150 225
Lth. to give rate of gain of cant of 1 1/2" per sec.	-	-	175	205	230	250
Lth. to give a gain of v^2/R of 1.75 = 0.0075 V	150 -	120 -	135 185	160 220	188 255	210 280 270

figures for a cant shown above

1.3 Design length.

In locations where the radius of curvature is severely restricted and therefore maximum speed, the length of transition should be kept close to the minimum. Hence to adopt transition lengths for preliminary design based on the curve for increase of v^2/R not greater than $a = 1.75 = 0.0075V$ and a cant gradient of not less than 1/300 should be satisfactory - refer Diagram No. 1. This gives the following:-

Radius of Circular Curve - ft.	150	200	250	300	350	400	450	500	600
Length of transition ft.	100 150	115 160	135 170	155 185	165 200	185 220	205 235	215 250	235 280

2. Overall dimensions of transition.

Horizontal transitions for underground tramways should be designed such that the radius of curvature varies strictly inversely as the length of transition. The Euler Spiral meets this requirement and the first term of its "expansion" gives the cubic spiral

$$y = \frac{x^3}{6RL}$$

If the angle of the transition is not great such that it may be assumed that $y = x$ we get the cubic parabola

$$y = \frac{x^3}{6RL}$$

Further work will however be based on the cubic spiral unless the desired accuracy requires the use of further terms of the above expansion; which of course will be necessary in the ultimate design.

2.1 Shift. Refer Diagram No. 2.

The shift tangent is defined as the tangent to the extended circular arc portion of the curve which is parallel to the straight track tangent.

The shift is defined as the distance the shift tangent is away from the straight track tangent.

2.2 Procedure for arriving at overall dimension.

The procedure is one of trial and correction.

Proceed thus:-

- (a) Assume a value for the minimum radius R
- (b) select corresponding length L of transition refer 1.3 above
- (c) determine the transition angle θ which for the Euler Spiral is given by the simple expression

$$\theta = \frac{L}{2R} \quad \text{radians}$$

- (d) determine from table 1 the corresponding value of S/L for the Euler Spiral where S = shift and hence find S (Reference Plane and Geodetic Surveying Part 1 - Clark).
- (e) locate the centre of the circular arc and hence locate the circular arc
- (f) determine from table 1 the corresponding value of C/L for the Euler Spiral where C = extension and hence find C.

Note: C is approximately equal to half L.

The transition curve may then be set out using the expansions,

$$y = \frac{l^3}{3(2RL)} - \frac{l^7}{7 \cdot 3 \cdot 2 \cdot (2RL)^3} + \frac{l^{11}}{11 \cdot 5 \cdot 4 \cdot 3 \cdot 2 \cdot (2RL)^5} -$$
$$x = l - \frac{l^5}{5 \cdot 2 \cdot (2RL)^2} + \frac{l^9}{9 \cdot 4 \cdot 3 \cdot 2 \cdot (2RL)^4} -$$

where l = length of arc corresponding to x, y.

If clearances are such as to permit a larger value for the minimum radius R repeat until a curve arrangement is obtained which will permit the maximum speed considered desirable
